Installing gophers One of the very first things you need to know before you begin work on a gopher hole is what exactly makes a gopher hole. A gopher's body consists of a thick outer shell made up of tightly packed, overlapping, circular ridges that range in width from a few millimetres to 3 cm (1½ in). The head of the gopher is merely a mass of muscles that make the ridges move up and down. From outside the gopher, the rounded form of the head and the small hole in the middle of the body look distinctly like a normal ant. The amount of gopher fur varies with food availability, with adults spending most of the year foraging for food and pup gophers having thinner, smoother coats for camouflage. Gophers usually stay about the same size throughout their lives, although young gophers are sometimes in sizes that range between small and medium, such as 3 to 5 cm (1½ in). Both sexes generally look alike. Their most obvious characteristic is the hole they dig, which can easily be seen in living tunnels, though the hole gets bigger as the gopher matures. Gophers usually live for five to six years, though they can be expected to live longer if there is no competition for food. The easiest way to install gophers is to purchase gophers for sale from an import store. You can also buy live gophers from a pet store or similar store. When the gophers are bought, they need to be shipped at room temperature. Place them in a suitable container so that they can stand upright on the bottom.
